

# HIBERNATE - BAG MAPPINGS

[http://www.tutorialspoint.com/hibernate/hibernate\\_bag\\_mapping.htm](http://www.tutorialspoint.com/hibernate/hibernate_bag_mapping.htm)

Copyright © tutorialspoint.com

A **Bag** is a java collection that stores elements without caring about the sequencing but allow duplicate elements in the list. A bag is a random grouping of the objects in the list.

A Collection is mapped with a <bag> element in the mapping table and initialized with java.util.ArrayList.

## Define RDBMS Tables:

Consider a situation where we need to store our employee records in EMPLOYEE table which will have following structure:

```
create table EMPLOYEE (  
  id INT NOT NULL auto_increment,  
  first_name VARCHAR(20) default NULL,  
  last_name VARCHAR(20) default NULL,  
  salary INT default NULL,  
  PRIMARY KEY (id)  
);
```

Further, assume each employee can have one or more certificate associated with him/her. We will store certificate related information in a separate table which has following structure:

```
create table CERTIFICATE (  
  id INT NOT NULL auto_increment,  
  certificate_name VARCHAR(30) default NULL,  
  employee_id INT default NULL,  
  PRIMARY KEY (id)  
);
```

There will be **one-to-many** relationship between EMPLOYEE and CERTIFICATE objects.

## Define POJO Classes:

Let us implement a POJO class **Employee** which will be used to persist the objects related to EMPLOYEE table and having a collection of certificates in **List** variable.

```
import java.util.*;  
  
public class Employee {  
  private int id;  
  private String firstName;  
  private String lastName;  
  private int salary;  
  private Collection certificates;  
  
  public Employee() {}  
  public Employee(String fname, String lname, int salary) {  
    this.firstName = fname;  
    this.lastName = lname;  
    this.salary = salary;  
  }  
  public int getId() {  
    return id;  
  }  
  public void setId( int id ) {  
    this.id = id;  
  }  
  public String getFirstName() {  
    return firstName;  
  }  
  public void setFirstName( String first_name ) {
```

```

        this.firstName = first_name;
    }
    public String getLastName() {
        return lastName;
    }
    public void setLastName( String last_name ) {
        this.lastName = last_name;
    }
    public int getSalary() {
        return salary;
    }
    public void setSalary( int salary ) {
        this.salary = salary;
    }

    public Collection getCertificates() {
        return certificates;
    }
    public void setCertificates( Collection certificates ) {
        this.certificates = certificates;
    }
}

```

We need to define another POJO class corresponding to CERTIFICATE table so that certificate objects can be stored and retrieved into the CERTIFICATE table.

```

public class Certificate{
    private int id;
    private String name;

    public Certificate() {}
    public Certificate(String name) {
        this.name = name;
    }
    public int getId() {
        return id;
    }
    public void setId( int id ) {
        this.id = id;
    }
    public String getName() {
        return name;
    }
    public void setName( String name ) {
        this.name = name;
    }
}

```

## Define Hibernate Mapping File:

Let us develop our mapping file which instructs Hibernate how to map the defined classes to the database tables. The <bag> element will be used to define the rule for the Collection used.

```

<?xml version="1.0" encoding="utf-8"?>
<!DOCTYPE hibernate-mapping PUBLIC
    "-//Hibernate/Hibernate Mapping DTD//EN"
    "http://www.hibernate.org/dtd/hibernate-mapping-3.0.dtd">

<hibernate-mapping>
    <class name="Employee" table="EMPLOYEE">
        <meta attribute="class-description">
            This class contains the employee detail.
        </meta>
        <id name="id" type="int" column="id">
            <generator />
        </id>
        <bag name="certificates" cascade="all">
            <key column="employee_id"/>

```

```

        <one-to-many />
    </bag>
    <property name="firstName" column="first_name" type="string"/>
    <property name="lastName" column="last_name" type="string"/>
    <property name="salary" column="salary" type="int"/>
</class>

<class name="Certificate" table="CERTIFICATE">
    <meta attribute="class-description">
        This class contains the certificate records.
    </meta>
    <id name="id" type="int" column="id">
        <generator />
    </id>
    <property name="name" column="certificate_name" type="string"/>
</class>

</hibernate-mapping>

```

You should save the mapping document in a file with the format <classname>.hbm.xml. We saved our mapping document in the file Employee.hbm.xml. You are already familiar with most of the mapping detail but let us see all the elements of mapping file once again:

- The mapping document is an XML document having **<hibernate-mapping>** as the root element which contains two <class> elements corresponding to each class.
- The **<class>** elements are used to define specific mappings from a Java classes to the database tables. The Java class name is specified using the **name** attribute of the class element and the database table name is specified using the **table** attribute.
- The **<meta>** element is optional element and can be used to create the class description.
- The **<id>** element maps the unique ID attribute in class to the primary key of the database table. The **name** attribute of the id element refers to the property in the class and the **column** attribute refers to the column in the database table. The **type** attribute holds the hibernate mapping type, this mapping types will convert from Java to SQL data type.
- The **<generator>** element within the id element is used to automatically generate the primary key values. Set the **class** attribute of the generator element is set to **native** to let hibernate pick up either **identity**, **sequence** or **hilo** algorithm to create primary key depending upon the capabilities of the underlying database.
- The **<property>** element is used to map a Java class property to a column in the database table. The **name** attribute of the element refers to the property in the class and the **column** attribute refers to the column in the database table. The **type** attribute holds the hibernate mapping type, this mapping types will convert from Java to SQL data type.
- The **<bag>** element is used to set the relationship between Certificate and Employee classes. We used the **cascade** attribute in the <bag> element to tell Hibernate to persist the Certificate objects at the same time as the Employee objects. The **name** attribute is set to the defined **Collection** variable in the parent class, in our case it is *certificates*.
- The **<key>** element is the column in the CERTIFICATE table that holds the foreign key to the parent object ie. table EMPLOYEE.
- The **<one-to-many>** element indicates that one Employee object relates to many Certificate objects and, as such, the Certificate object must have a Employee parent associated with it. You can use either **<one-to-one>**, **<many-to-one>** or **<many-to-many>** elements based on your requirement.

## Create Application Class:

Finally, we will create our application class with the main method to run the application. We will use this application to save few Employee's records alongwith their certificates and then we will apply CRUD operations on those records.

```
import java.util.*;
```

```

import org.hibernate.HibernateException;
import org.hibernate.Session;
import org.hibernate.Transaction;
import org.hibernate.SessionFactory;
import org.hibernate.cfg.Configuration;

public class ManageEmployee {
    private static SessionFactory factory;
    public static void main(String[] args) {
        try{
            factory = new Configuration().configure().buildSessionFactory();
        }catch (Throwable ex) {
            System.err.println("Failed to create sessionFactory object." + ex);
            throw new ExceptionInInitializerError(ex);
        }
        ManageEmployee ME = new ManageEmployee();
        /* Let us have a set of certificates for the first employee */
        ArrayList set1 = new ArrayList();
        set1.add(new Certificate("MCA"));
        set1.add(new Certificate("MBA"));
        set1.add(new Certificate("PMP"));

        /* Add employee records in the database */
        Integer empID1 = ME.addEmployee("Manoj", "Kumar", 4000, set1);

        /* Another set of certificates for the second employee */
        ArrayList set2 = new ArrayList();
        set2.add(new Certificate("BCA"));
        set2.add(new Certificate("BA"));

        /* Add another employee record in the database */
        Integer empID2 = ME.addEmployee("Dilip", "Kumar", 3000, set2);

        /* List down all the employees */
        ME.listEmployees();

        /* Update employee's salary records */
        ME.updateEmployee(empID1, 5000);

        /* Delete an employee from the database */
        ME.deleteEmployee(empID2);

        /* List down all the employees */
        ME.listEmployees();
    }

    /* Method to add an employee record in the database */
    public Integer addEmployee(String fname, String lname,
                               int salary, ArrayList cert){
        Session session = factory.openSession();
        Transaction tx = null;
        Integer employeeID = null;
        try{
            tx = session.beginTransaction();
            Employee employee = new Employee(fname, lname, salary);
            employee.setCertificates(cert);
            employeeID = (Integer) session.save(employee);
            tx.commit();
        }catch (HibernateException e) {
            if (tx!=null) tx.rollback();
            e.printStackTrace();
        }finally {
            session.close();
        }
        return employeeID;
    }
}

```

```

/* Method to list all the employees detail */
public void listEmployees( ){
    Session session = factory.openSession();
    Transaction tx = null;
    try{
        tx = session.beginTransaction();
        List employees = session.createQuery("FROM Employee").list();
        for (Iterator iterator1 =
            employees.iterator(); iterator1.hasNext();){
            Employee employee = (Employee) iterator1.next();
            System.out.print("First Name: " + employee.getFirstName());
            System.out.print("  Last Name: " + employee.getLastName());
            System.out.println("  Salary: " + employee.getSalary());
            Collection certificates = employee.getCertificates();
            for (Iterator iterator2 =
                certificates.iterator(); iterator2.hasNext();){
                Certificate certName = (Certificate) iterator2.next();
                System.out.println("Certificate: " + certName.getName());
            }
        }
        tx.commit();
    }catch (HibernateException e) {
        if (tx!=null) tx.rollback();
        e.printStackTrace();
    }finally {
        session.close();
    }
}

/* Method to update salary for an employee */
public void updateEmployee(Integer EmployeeID, int salary ){
    Session session = factory.openSession();
    Transaction tx = null;
    try{
        tx = session.beginTransaction();
        Employee employee =
            (Employee)session.get(Employee.class, EmployeeID);
        employee.setSalary( salary );
        session.update(employee);
        tx.commit();
    }catch (HibernateException e) {
        if (tx!=null) tx.rollback();
        e.printStackTrace();
    }finally {
        session.close();
    }
}

/* Method to delete an employee from the records */
public void deleteEmployee(Integer EmployeeID){
    Session session = factory.openSession();
    Transaction tx = null;
    try{
        tx = session.beginTransaction();
        Employee employee =
            (Employee)session.get(Employee.class, EmployeeID);
        session.delete(employee);
        tx.commit();
    }catch (HibernateException e) {
        if (tx!=null) tx.rollback();
        e.printStackTrace();
    }finally {
        session.close();
    }
}
}

```

## Compilation and Execution:

Here are the steps to compile and run the above mentioned application. Make sure you have set PATH and CLASSPATH appropriately before proceeding for the compilation and execution.

- Create hibernate.cfg.xml configuration file as explained in configuration chapter.
- Create Employee.hbm.xml mapping file as shown above.
- Create Employee.java source file as shown above and compile it.
- Create Certificate.java source file as shown above and compile it.
- Create ManageEmployee.java source file as shown above and compile it.
- Execute ManageEmployee binary to run the program.

You would get following result on the screen, and same time records would be created in EMPLOYEE and CERTIFICATE tables. You can see certificates has been sorted in reverse order. You can try by changing your mapping file, simply set **sort="natural"** and execute your program and compare the results.

```
$java ManageEmployee
.....VARIOUS LOG MESSAGES WILL DISPLAY HERE.....

First Name: Manoj  Last Name: Kumar  Salary: 4000
Certificate: MCA
Certificate: MBA
Certificate: PMP
First Name: Dilip  Last Name: Kumar  Salary: 3000
Certificate: BCA
Certificate: BA
First Name: Manoj  Last Name: Kumar  Salary: 5000
Certificate: MCA
Certificate: MBA
Certificate: PMP
```

If you check your EMPLOYEE and CERTIFICATE tables, they should have following records:

```
mysql> select * from EMPLOYEE;
+----+-----+-----+-----+
| id | first_name | last_name | salary |
+----+-----+-----+-----+
| 53 | Manoj      | Kumar     | 5000   |
+----+-----+-----+-----+
1 row in set (0.00 sec)

mysql> select * from CERTIFICATE;
+----+-----+-----+
| id | certificate_name | employee_id |
+----+-----+-----+
| 11 | MCA              | 53          |
| 12 | MBA              | 53          |
| 13 | PMP              | 53          |
+----+-----+-----+
3 rows in set (0.00 sec)

mysql>
```
