C# - PREPROCESSOR DIRECTIVES

The preprocessor directives give instruction to the compiler to preprocess the information before actual compilation starts.

All preprocessor directives begin with #, and only white-space characters may appear before a preprocessor directive on a line. Preprocessor directives are not statements, so they do not end with a semicolon ; .

C# compiler does not have a separate preprocessor; however, the directives are processed as if there was one. In C# the preprocessor directives are used to help in conditional compilation. Unlike C and C++ directives, they are not used to create macros. A preprocessor directive must be the only instruction on a line.

Preprocessor Directives in C#

The following table lists the preprocessor directives available in C#:

Preprocessor Directive	Description.
#define	It defines a sequence of characters, called symbol.
#undef	It allows you to undefine a symbol.
#if	It allows testing a symbol or symbols to see if they evaluate to true.
#else	It allows to create a compound conditional directive, along with #if.
#elif	It allows creating a compound conditional directive.
#endif	Specifies the end of a conditional directive.
#line	It lets you modify the compiler's line number and *optionally* the file name output for errors and warnings.
#error	It allows generating an error from a specific location in your code.
#warning	It allows generating a level one warning from a specific location in your code.
#region	It lets you specify a block of code that you can expand or collapse when using the outlining feature of the Visual Studio Code Editor.
#endregion	It marks the end of a #region block.

The #define Preprocessor

The #define preprocessor directive creates symbolic constants.

#define lets you define a symbol such that, by using the symbol as the expression passed to the #if directive, the expression evaluates to true. Its syntax is as follows:

```
#define symbol
```

The following program illustrates this:

```
#define PI
using System;
namespace PreprocessorDAppl
```

```
{
   class Program
   {
      static void Main(string[] args)
      {
         #if (PI)
            Console.WriteLine("PI is defined");
         #else
            Console.WriteLine("PI is not defined");
         #endif
         Console.ReadKey();
      }
   }
}
```

When the above code is compiled and executed, it produces the following result:

```
PI is defined
```

Conditional Directives

You can use the #if directive to create a conditional directive. Conditional directives are useful for testing a symbol or symbols to check if they evaluate to true. If they do evaluate to true, the compiler evaluates all the code between the #if and the next directive.

Syntax for conditional directive is:

```
#if symbol [operator symbol]...
```

Where, *symbol* is the name of the symbol you want to test. You can also use true and false or prepend the symbol with the negation operator.

The *operator symbol* is the operator used for evaluating the symbol. Operators could be either of the following:

- == *equality*
- != *inequality*
- && *and*
- || *or*

You can also group symbols and operators with parentheses. Conditional directives are used for compiling code for a debug build or when compiling for a specific configuration. A conditional directive beginning with a **#if** directive must explicitly be terminated with a **#endif** directive.

The following program demonstrates use of conditional directives:

```
#define DEBUG
#define VC_V10
using System;
public class TestClass
{
   public static void Main()
   {
      #if (DEBUG && !VC_V10)
         Console.WriteLine("DEBUG is defined");
      #elif (!DEBUG && VC_V10)
         Console.WriteLine("VC_V10 is defined");
      #elif (DEBUG && VC_V10)
         Console.WriteLine("DEBUG and VC_V10 are defined");
      #else
         Console.WriteLine("DEBUG and VC_V10 are not defined");
      #endif
      Console.ReadKey();
   }
```

```
}
```

When the above code is compiled and executed, it produces the following result:

```
DEBUG and VC_V10 are defined
```
