Independent sets are represented in sets, in which:

- there should not be **any edges adjacent to each other**. There should not be any common vertex between any two edges.
- there should not be **any vertices adjacent to each other**. There should not be any common edge between any two vertices.

### Independent Line Set

Let ‘G’ = V, E be a graph. A subset L of E is called an independent line set of ‘G’ if two edges in L are adjacent. Such a set is called an independent line set.

#### Example

Let us consider the following subsets −

- \( L_1 = \{a, b\} \)
- \( L_2 = \{a, b\} \cup \{c, e\} \)
- \( L_3 = \{a, d\} \cup \{b, c\} \)

In this example, the subsets \( L_2 \) and \( L_3 \) are clearly not the adjacent edges in the given graph. They are independent line sets. However \( L_1 \) is not an independent line set, as for making an independent line set, there should be at least two edges.

### Maximal Independent Line Set

An independent line set is said to be the maximal independent line set of a graph ‘G’ if no other edge of ‘G’ can be added to ‘L’.

#### Example
Let us consider the following subsets −

\[ L_1 = \{a, b\} \]
\[ L_2 = \{\{b, e\}, \{c, f\}\} \]
\[ L_3 = \{\{a, e\}, \{b, c\}, \{d, f\}\} \]
\[ L_4 = \{\{a, b\}, \{c, f\}\} \]

L₂ and L₃ are maximal independent line sets/maximal matching. As for only these two subsets, there is no chance of adding any other edge which is not an adjacent. Hence these two subsets are considered as the maximal independent line sets.

**Maximum Independent Line Set**

A maximum independent line set of ‘G’ with maximum number of edges is called a maximum independent line set of ‘G’.

**Example**

Let us consider the following subsets −

\[ L_1 = \{a, b\} \]
\[ L_2 = \{\{b, e\}, \{c, f\}\} \]
\[ L_3 = \{\{a, e\}, \{b, c\}, \{d, f\}\} \]
\[ L_4 = \{\{a, b\}, \{c, f\}\} \]

L₃ is the maximum independent line set of G with maximum edges which are not the adjacent edges in graph and is denoted by \( \beta_1 = 3 \).

**Note** – For any graph G with no isolated vertex,

\[ \alpha_1 + \beta_1 = \text{number of vertices in a graph} = |V| \]

**Example**

Line covering number of \( K_n/C_n/w_n \),

\[ \alpha_1 = \left\lfloor \frac{n}{2} \right\rfloor \begin{cases} \frac{n}{2} & \text{if } n \text{ is even} \\ \frac{n+1}{2} & \text{if } n \text{ is odd} \end{cases} \]

Line independent number *Matching number* = \( \beta_1 = \lfloor n / 2 \rfloor \alpha_1 \) plus; \( \beta_1 = n \)
**Independent Vertex Set**

Let ‘G’ = \( V, E \) be a graph. A subset of ‘V’ is called an independent set of ‘G’ if no two vertices in ‘S’ are adjacent.

**Example**

Consider the following subsets from the above graphs −

\[
\begin{align*}
S_1 &= \{e\} \\
S_2 &= \{e, f\} \\
S_3 &= \{a, g, c\} \\
S_4 &= \{e, d\}
\end{align*}
\]

Clearly \( S_1 \) is not an independent vertex set, because for getting an independent vertex set, there should be at least two vertices in the from a graph. But here it is not that case. The subsets \( S_2, S_3, \) and \( S_4 \) are the independent vertex sets because there is no vertex that is adjacent to any one vertex from the subsets.

**Maximal Independent Vertex Set**

Let ‘G’ be a graph, then an independent vertex set of ‘G’ is said to be maximal if no other vertex of ‘G’ can be added to ‘S’.

**Example**
Consider the following subsets from the above graphs.

\[
S_1 = \{ e \} \\
S_2 = \{ e, f \} \\
S_3 = \{ a, g, c \} \\
S_4 = \{ e, d \}
\]

\( S_2 \) and \( S_3 \) are maximal independent vertex sets of \( G \). In \( S_1 \) and \( S_4 \), we can add other vertices; but in \( S_2 \) and \( S_3 \), we cannot add any other vertex.

**Maximum Independent Vertex Set**

A maximal independent vertex set of \( G \) with maximum number of vertices is called as the maximum independent vertex set.

**Example**

Consider the following subsets from the above graph –

\[
S_1 = \{ e \} \\
S_2 = \{ e, f \} \\
S_3 = \{ a, g, c \} \\
S_4 = \{ e, d \}
\]

Only \( S_3 \) is the maximum independent vertex set, as it covers the highest number of vertices. The number of vertices in a maximum independent vertex set of \( G \) is called the independent vertex number of \( G \) (\( \beta_2 \)).

**Example**

For the complete graph \( K_n \),

- Vertex covering number = \( \alpha_2 = n-1 \)
- Vertex independent number = \( \beta_2 = 1 \)

You have \( \alpha_2 \) &plus; \( \beta_2 = n \)

In a complete graph, each vertex is adjacent to its remaining \( (n-1) \) vertices. Therefore, a maximum independent set of \( K_n \) contains only one vertex.

Therefore, \( \beta_2 = 1 \)

and \( \alpha_2 = |V| - \beta_2 = n-1 \)

**Note** – For any graph \( G = V, E \)
\[ \alpha_2 + \beta_2 = |v| \]

If \( S \) is an independent vertex set of \( G \), then \( V - S \) is a vertex cover of \( G \).
