LEARN MAKEFILE
unix makefile

www.tutorialspoint.com

About the Tutorial

Makefile is a program building tool which runs on Unix, Linux, and their flavors. It aids in simplifying building program executables that may need various modules. To determine how the modules need to be compiled or recompiled together, make takes the help of user-defined makefiles. This tutorial should enhance your knowledge about the structure and utility of makefile.

Audience

Makefile guides the make utility while compiling and linking program modules. Anyone who wants to compile their programs using the make utility and wants to gain knowledge on makefile should read this tutorial.

Prerequisites

This tutorial expects good understanding of programming language such as C and C++. The reader is expected to have knowledge of linking, loading concepts, and also the knowledge of compiling and executing programs in Unix/Linux environment.

9. EXAMPLE ............................................................................................................................... 18
Compiling the source code files can be tiring, especially when you have to include several source files and type the compiling commands every time. Makefiles are the solution to simplify this task.

Makefiles are special format files that help build and manage the projects automatically.

For example, let’s assume we have the following source files.

- main.cpp
- hello.cpp
- factorial.cpp
- functions.h

**main.cpp**
The following is the code for main.cpp source file:

```cpp
#include <iostream.h>
#include "functions.h"

int main()
{
    print_hello();
    cout << endl;
    cout << "The factorial of 5 is " << factorial(5) << endl;
    return 0;
}
```

**hello.cpp**
The code given below is for hello.cpp source file:

```cpp
#include <iostream.h>
#include "functions.h"

void print_hello()
{
    cout << "Hello World!";
}
```
factorial.cpp
The code for factorial.cpp is given below:

```c
#include "functions.h"

int factorial(int n){
    if(n!=1){
        return(n * factorial(n-1));
    }
    else return 1;
}
```

functions.h
The following is the code for functions.h:

```c
void print_hello();
int factorial(int n);
```

The trivial way to compile the files and obtain an executable is by running the following command:

```
CC  main.cpp hello.cpp factorial.cpp -o hello
```

This command generates hello binary. In this example, we have only four files and we know the sequence of the function calls. Hence, it is feasible to type the above command and prepare a final binary.

However, for a large project where we have thousands of source code files, it becomes difficult to maintain the binary builds.

The make command allows you to manage large programs or groups of programs. As you begin to write large programs, you notice that re-compiling large programs takes longer time than re-compiling short programs. Moreover, you notice that you usually only work on a small section of the program such as a single function, and much of the remaining program is unchanged.

In the subsequent section, we will see how to prepare a makefile for our project.
The `make` program allows you to use macros, which are similar to variables. Macros are defined in a Makefile as `=` pairs. An example has been shown below:

```
MACROS= -me
PSROFF= groff -Tps
DITROFF= groff -Tdvi
CFLAGS= -O -systype bsd43
LIBS = "-lncurses -lm -lsdl"
MYFACE = "*:*)"
```

### Special Macros

Before issuing any command in a target rule set, there are certain special macros predefined:

- `$@` is the name of the file to be made.
- `$?` is the name of the changed dependents.

For example, we could use a rule as follows:

```
hello: main.cpp hello.cpp factorial.cpp

$(CC) $(CFLAGS) $? $(LDFLAGS) -o $@
```

Alternatively:

```
hello: main.cpp hello.cpp factorial.cpp

$(CC) $(CFLAGS) $@.cpp $(LDFLAGS) -o $@
```

In this example, `$@` represents `hello` and `$?` or `@$`.cpp picks up all the changed source files.

There are two more special macros used in the implicit rules. They are:

- `$<` the name of the related file that caused the action.
- `$*` the prefix shared by target and dependent files.

Common implicit rule is given below for the construction of `.o` (object) files out of `.cpp` (source files).

```
.o.cpp:

$(CC) $(CFLAGS) -c $<
```

Alternatively:
.o.cpp:

$(CC) $(CFLAGS) -c *.c

Conventional Macros

There are various default macros. You can see them by typing "make -p" to print out the defaults. Most are pretty obvious from the rules in which they are used.

These predefined variables, i.e., macros used in implicit rules fall into two classes. They are as follows:

1. Macros that are names of programs (such as CC).
2. Macros that contain arguments of the programs (such as CFLAGS).

Below is a table of some of the common variables used as names of programs in built-in rules of makefiles:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AR</td>
<td>Archive-maintaining program; default is 'ar'.</td>
</tr>
<tr>
<td>AS</td>
<td>Program to compile assembly files; default is 'as'.</td>
</tr>
<tr>
<td>CC</td>
<td>Program to compile C programs; default is 'cc'.</td>
</tr>
<tr>
<td>CO</td>
<td>Program to check out files from RCS; default is 'co'.</td>
</tr>
<tr>
<td>CXX</td>
<td>Program to compile C++ programs; default is 'g++'.</td>
</tr>
<tr>
<td>CPP</td>
<td>Program to run the C preprocessor, with results to standard output; default is '$(CC) -E' .</td>
</tr>
<tr>
<td>FC</td>
<td>Program to compile or preprocessing Fortran and Ratfor programs; default is 'f77'.</td>
</tr>
<tr>
<td>GET</td>
<td>Program to extract a file from SCCS; default is 'get'.</td>
</tr>
<tr>
<td>LEX</td>
<td>Program to use to turn Lex grammars into source code; default is 'lex'.</td>
</tr>
<tr>
<td>YACC</td>
<td>Program to use to turn Yacc grammars into source code; default is 'yacc'.</td>
</tr>
<tr>
<td>LINT</td>
<td>Program to use to run lint on source code; default is 'lint'.</td>
</tr>
<tr>
<td>M2C</td>
<td>Program to use to compile Modula-2 source code; default is 'm2c'.</td>
</tr>
<tr>
<td>PC</td>
<td>Program to compile Pascal programs; default is 'pc'.</td>
</tr>
<tr>
<td>---------</td>
<td>-----------------------------------------------------</td>
</tr>
<tr>
<td>MAKEINFO</td>
<td>Program to convert a Texinfo source file into an Info file; default is 'makeinfo'.</td>
</tr>
<tr>
<td>TEX</td>
<td>Program to make TeX dvi files from TeX source; default is 'tex'.</td>
</tr>
<tr>
<td>TEXI2DVI</td>
<td>Program to make TeX dvi files from Texinfo source; default is 'texi2dvi'.</td>
</tr>
<tr>
<td>WEAVE</td>
<td>Program to translate Web into TeX; default is 'weave'.</td>
</tr>
<tr>
<td>CWEAVE</td>
<td>Program to translate C Web into TeX; default is 'cweave'.</td>
</tr>
<tr>
<td>TANGLE</td>
<td>Program to translate Web into Pascal; default is 'tangle'.</td>
</tr>
<tr>
<td>CTANGLE</td>
<td>Program to translate C Web into C; default is 'ctangle'.</td>
</tr>
<tr>
<td>RM</td>
<td>Command to remove a file; default is 'rm -f'.</td>
</tr>
</tbody>
</table>

Here is a table of variables whose values are additional arguments for the programs above. The default values for all of these is the empty string, unless otherwise noted.

<table>
<thead>
<tr>
<th>ARFLAGS</th>
<th>Flags to give the archive-maintaining program; default is 'rv'.</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASFLAGS</td>
<td>Extra flags to give to the assembler when explicitly invoked on a '.s' or '.S' file.</td>
</tr>
<tr>
<td>CFLAGS</td>
<td>Extra flags to give to the C compiler.</td>
</tr>
<tr>
<td>CXXFLAGS</td>
<td>Extra flags to give to the C compiler.</td>
</tr>
<tr>
<td>COFLAGS</td>
<td>Extra flags to give to the RCS co program.</td>
</tr>
<tr>
<td>CPPFLAGS</td>
<td>Extra flags to give to the C preprocessor and programs, which use it (such as C and Fortran compilers).</td>
</tr>
<tr>
<td>FFLAGS</td>
<td>Extra flags to give to the Fortran compiler.</td>
</tr>
<tr>
<td>GFLAGS</td>
<td>Extra flags to give to the SCCS get program.</td>
</tr>
<tr>
<td>Variable</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>LDFLAGS</td>
<td>Extra flags to give to compilers when they are supposed to invoke the linker, 'ld'.</td>
</tr>
<tr>
<td>LFLAGS</td>
<td>Extra flags to give to Lex.</td>
</tr>
<tr>
<td>YFLAGS</td>
<td>Extra flags to give to Yacc.</td>
</tr>
<tr>
<td>PFLAGS</td>
<td>Extra flags to give to the Pascal compiler.</td>
</tr>
<tr>
<td>RFLAGS</td>
<td>Extra flags to give to the Fortran compiler for Ratfor programs.</td>
</tr>
<tr>
<td>LINTFLAGS</td>
<td>Extra flags to give to lint.</td>
</tr>
</tbody>
</table>

**NOTE**: You can cancel all variables used by implicit rules with the '-R' or '--no-built-in-variables' option.

You can also define macros at the command line as shown below:

```
make CPP = /home/courses/cop4530/spring02
```
It is very common that a final binary will be dependent on various source codes and source header files. Dependencies are important because they allow make to know about the source for any target. Let us consider the following example:

```
hello: main.o factorial.o hello.o
    $(CC) main.o factorial.o hello.o -o hello
```

Here, we give an input to make that hello is dependent on main.o, factorial.o, and hello.o files. Hence, whenever there is a change in any of these object files, make will take action.

At the same time, we need to tell the make how to prepare .o files. Hence, we define those dependencies also as follows:

```
main.o: main.cpp functions.h
    $(CC) -c main.cpp

factorial.o: factorial.cpp functions.h
    $(CC) -c factorial.cpp

hello.o: hello.cpp functions.h
    $(CC) -c hello.cpp
```
4. RULES

We will now learn the rules for Makefile.

The general syntax of a Makefile target rule is given below:

```
  target [target...] : [dependent ....]
      [ command ...]
```

In the above code, the arguments in brackets are optional and ellipsis means one or more. Here, note that the tab to preface each command is required.

A simple example is given below where you define a rule to make your target hello from three other files.

```
hello: main.o factorial.o hello.o
    $(CC) main.o factorial.o hello.o -o hello
```

**NOTE:** In this example, you define rules to make all object files from the source files.

The semantics is very simple. When you say "make target", make finds the target rule that applies; and if any of the dependents are newer than the target, make executes the commands one at a time (after macro substitution). If any dependents have to be made, that happens first (so you have a recursion).

**Make** terminates if any command returns a failure status. The following rule will be shown in such case:

```
  clean:
      -rm *.o *~ core paper
```

**Make** ignores the returned status on command lines that begin with a dash. For example, who cares if there is no core file?

**Make** echoes the commands, after macro substitution to show you what is happening. Sometimes you might want to turn that off. For example:

```
install:
    @echo You must be root to install
```

People have come to expect certain targets in Makefiles. You should always browse first. However, it is reasonable to expect that the targets all (or just make), install, and clean is found.

- **make all** – It compiles everything so that you can do local testing before installing applications.
- **make install** – It installs applications at right places.
- **make clean** – It cleans applications, gets rid of the executables, any temporary files, object files, etc.
**Makefile Implicit Rules**

The command is one that ought to work in all cases where we build an executable x out of the source code x.cpp. This can be stated as an implicit rule:

```
.cpp:
   $(CC) $(CFLAGS) $@.cpp $(LDFLAGS) -o $@
```

This implicit rule says how to make x out of x.c -- run cc on x.c and call the output x. The rule is implicit because no particular target is mentioned. It can be used in all cases.

Another common implicit rule is for the construction of .o (object) files out of .cpp (source files).

```
.o.cpp:
   $(CC) $(CFLAGS) -c $<
```

Alternatively:

```
.o.cpp:
   $(CC) $(CFLAGS) -c *.cpp
```
Make can automatically create a.o file, using cc -c on the corresponding .c file. These rules are built-in the make, and you can take this advantage to shorten your Makefile. If you indicate just the .h files in the dependency line of the Makefile on which the current target is dependent on, make will know that the corresponding .c file is already required. You do not have to include the command for the compiler. This reduces the Makefile further, as shown below:

```
OBJECTS = main.o hello.o factorial.o
hello: $(OBJECTS)
    cc $(OBJECTS) -o hello
hellp.o: functions.h
main.o: functions.h
factorial.o: functions.h
```

Make uses a special target, named .SUFFIXES to allow you to define your own suffixes. For example, refer the dependency line given below:

```
.SUFFIXES: .foo .bar
```

It informs make that you will be using these special suffixes to make your own rules. Similar to how make already knows to make a .o file from a .c file, you can define rules in the following manner:

```
.foo.bar:
    tr '[A-Z][a-z]' '[N-Z][A-M][n-z][a-m]' < $< > $@
.c.o:
    $(CC) $(CFLAGS) -c $<
```

The first rule allows you to create a .bar file from a .foo file. It basically scrambles the file. The second rule is the default rule used by make to create a.o file from a .c file.
There are numerous directives available in various forms. The `make` program on your system may not support all the directives. So please check if your `make` supports the directives we are explaining here. **GNU make** supports these directives.

### Conditional Directives

The conditional directives are:

- The `ifeq` directive begins the conditional, and specifies the condition. It contains two arguments, separated by a comma and surrounded by parentheses. Variable substitution is performed on both arguments and then they are compared. The lines of the makefile following the `ifeq` are obeyed if the two arguments match; otherwise they are ignored.

- The `ifneq` directive begins the conditional, and specifies the condition. It contains two arguments, separated by a comma and surrounded by parentheses. Variable substitution is performed on both arguments and then they are compared. The lines of the makefile following the `ifneq` are obeyed if the two arguments do not match; otherwise they are ignored.

- The `ifdef` directive begins the conditional, and specifies the condition. It contains single argument. If the given argument is true then condition becomes true.

- The `ifndef` directive begins the conditional, and specifies the condition. It contains single argument. If the given argument is false then condition becomes true.

- The `else` directive causes the following lines to be obeyed if the previous conditional failed. In the example above, this means, the second alternative linking command is used whenever the first alternative is not used. It is optional to have an else in a conditional.

- The `endif` directive ends the conditional. Every conditional must end with an `endif`.

### Syntax of Conditionals Directives

The syntax of a simple conditional with no else is as follows:

```
conditional-directive
  text-if-true
  endif
```

The `text-if-true` may be any lines of text, to be considered as part of the makefile if the condition is true. If the condition is false, no text is used instead.

The syntax of a complex conditional is as follows:

```
conditional-directive
  text-if-true
```

---

**tutorialspoint**

11
If the condition is true, text-if-true is used; otherwise, text-if-false is used. The text-if-false can be any number of lines of text.

The syntax of the conditional-directive is same whether the conditional is simple or complex. There are four different directives that test various conditions. They are as given below:

```
ifeq (arg1, arg2)
ifeq 'arg1' 'arg2'
ifeq "arg1" "arg2"
ifeq "arg1" 'arg2'
ifeq 'arg1' "arg2"
```

Opposite directives of the above conditions are as follows:

```
ifneq (arg1, arg2)
ifneq 'arg1' 'arg2'
ifneq "arg1" "arg2"
ifneq "arg1" 'arg2'
ifneq 'arg1' "arg2"
```

### Example of Conditionals Directives

```makefile
libs_for_gcc = -lgnu
normal_libs =

foo: $(objects)
ifeq ($(CC),gcc)
    $(CC) -o foo $(objects) $(libs_for_gcc)
else
    $(CC) -o foo $(objects) $(normal_libs)
endif
```

### The include Directive

The **include directive** allows **make** to suspend reading the current makefile and read one or more other makefiles before continuing. The directive is a line in the makefile that looks as follows:

```
include filenames...
```
The filenames can contain shell file name patterns. Extra spaces are allowed and ignored at 
the beginning of the line, but a tab is not allowed. For example, if you have three `.mk` files 
namely, `a.mk`, `b.mk`, and `c.mk`, and $(bar), then it expands to bish bash, and then the 
following expression.

```
included foo *.mk $(bar)
```

is equivalent to

```
included foo a.mk b.mk c.mk bish bash
```

When the make processes an include directive, it suspends reading of the included makefile 
and reads from each listed file in turn. When that is finished, make resumes reading the 
makefile in which the directive appears.

**The override Directive**

If a variable has been set with a command argument, then ordinary assignments in the 
makefile are ignored. If you want to set the variable in the makefile even though it was set 
with a command argument, you can use an override directive, which is a line that looks as 
follows:

```
override variable = value
```

or

```
override variable := value
```
The **make** program is an intelligent utility and works based on the changes you do in your source files. If you have four files `main.cpp`, `hello.cpp`, `factorial.cpp`, and `functions.h`, then all the remaining files are dependent on `functions.h`, and `main.cpp` is dependent on both `hello.cpp` and `factorial.cpp`. Hence if you make any changes in `functions.h`, then the **make** recompiles all the source files to generate new object files. However, if you make any change in `main.cpp`, as this is not dependent on any other file, then only `main.cpp` file is recompiled, and `hello.cpp` and `factorial.cpp` are not.

While compiling a file, the **make** checks its object file and compares the time stamps. If the source file has a newer time stamp than the object file, then it generates new object file assuming that the source file has been changed.

### Avoiding Recomputation

There may be a project consisting of thousands of files. Sometimes you may have changed a source file but you may not want to recompile all the files that depend on it. For example, suppose, you add a macro or a declaration to a header file, on which the other files depend. Being conservative, the **make** assumes that any change in the header file requires recompilation of all dependent files, but you know that they do not need recompilation and you would rather not waste your time waiting for them to compile.

If you anticipate the problem before changing the header file, you can use the `-t` flag. This flag tells **make** not to run the commands in the rules, but rather to mark the target up to date by changing its last-modification date. You need to follow the below given procedure:

1. Use the command 'make' to recompile the source files that really need recompilation.
2. Make the changes in the header files.
3. Use the command 'make -t' to mark all the object files as up to date. The next time you run make, the changes in the header files do not cause any recompilation.

If you have already changed the header file at a time when some files do need recompilation, it is too late to do this. Instead, you can use the '-o file' flag, which marks a specified file as "old". This means, the file itself will not be remade, and nothing else will be remade on its account. You need to follow this procedure:

1. Recompile the source files that need compilation for reasons independent of the particular header file, with 'make -o headerfile'. If several header files are involved, use a separate '-o' option for each header file.
2. Update all the object files with 'make -t'.

---

7. **RECOMPIILATION**

---
In this chapter, we shall look into various other features of Makefile.

**Recursive Use of Make**

Recursive use of `make` means using `make` as a command in a makefile. This technique is useful when you want separate makefiles for various subsystems that compose a larger system. For example, suppose, you have a subdirectory named 'subdir' which has its own makefile, and you would like the containing directory's makefile to run `make` on the subdirectory. You can do it by writing the below code:

```
subsystem:
    cd subdir && $(MAKE)
```

or, equivalently

```
subsystem:
    $(MAKE) -C subdir
```

You can write recursive `make` commands just by copying this example. However, you need to know about how they work and why, and how the sub-make relates to the top-level make.

**Communicating Variables to a Sub-Make**

Variable values of the top-level `make` can be passed to the sub-make through the environment by explicit request. These variables are defined in the sub-make as defaults. You cannot override what is specified in the makefile used by the sub-make makefile unless you use the '-e' switch.

To pass down or export a variable, `make` adds the variable and its value to the environment for running each command. The sub-make, in turn, uses the environment to initialize its table of variable values.

The special variables SHELL and MAKEFLAGS are always exported (unless you unexport them). MAKEFILES is exported if you set it to anything.

If you want to export specific variables to a sub-make, use the export directive, as shown below:

```
export variable ...
```

If you want to prevent a variable from being exported, use the unexport directive, as shown below:
The Variable MAKEFILES

If the environment variable MAKEFILES is defined, make considers its value as a list of names (separated by whitespace) of additional makefiles to be read before others. This works much like the include directive: various directories are searched for those files.

The main use of MAKEFILES is in communication between recursive invocations of the make.

Including Header File from Different Directories

If you have put the header files in different directories and you are running make in a different directory, then it is required to provide the path of header files. This can be done using -I option in makefile. Assuming that functions.h file is available in /home/tutorialspoint/header folder and rest of the files are available in /home/tutorialspoint/src/ folder, then the makefile would be written as follows:

```makefile
INCLUDES = -I "./home/tutorialspoint/header"
CC = gcc
LIBS = -lm
CFLAGS = -g -Wall
OBJ = main.o factorial.o hello.o

hello: ${OBJ}
   ${CC} ${CFLAGS} ${INCLUDES} -o $@ ${OBJS} ${LIBS}
.cpp.o:
   ${CC} ${CFLAGS} ${INCLUDES} -c <
```

Appending More Text to Variables

Often it is useful to add more text to the value of a variable already defined. You do this with a line containing `+=', as shown:

```makefile
objects += another.o
```

It takes the value of the variable objects, and adds the text 'another.o' to it, preceded by a single space as shown below.

```makefile
objects = main.o hello.o factorial.o
objects += another.o
```

The above code sets objects to 'main.o hello.o factorial.o another.o'.

Using '+=' is similar to:
objects = main.o hello.o factorial.o
objects := $(objects) another.o

Continuation Line in Makefile
If you do not like too big lines in your Makefile, then you can break your line using a back-slash "\" as shown below:

OBJ = main.o factorial.o \ hello.o

is equivalent to

OBJ = main.o factorial.o hello.o

Running Makefile from Command Prompt
If you have prepared the Makefile with name "Makefile", then simply write make at command prompt and it will run the Makefile file. But if you have given any other name to the Makefile, then use the following command:

make -f your-makefile-name
The following is an example of the Makefile for compiling the hello program. This program consists of three files main.cpp, factorial.cpp, and hello.cpp.

```makefile
# Define required macros here
SHELL = /bin/sh

OBJ = main.o factorial.o hello.o
CFLAG = -Wall -g
CC = gcc
INCLUDE =
LIBS = -lm

hello:${OBJ}
    ${CC} ${CFLAGS} ${INCLUDE} -o ${OBJ} ${OBJ} ${LIBS}

clean:
    -rm -f *.o core *.core

.cpp.o:
    ${CC} ${CFLAGS} ${INCLUDE} -c $<
```

Now you can build the program hello using the `make`. If you issue a command ‘make clean’, it removes all the object files and core files present in the current directory.
