

SERVLETS - LIFE CYCLE

A servlet life cycle can be defined as the entire process from its creation till the destruction. The following are the paths followed by a servlet

- The servlet is initialized by calling the **init** method.
- The servlet calls **service** method to process a client's request.
- The servlet is terminated by calling the **destroy** method.
- Finally, servlet is garbage collected by the garbage collector of the JVM.

Now let us discuss the life cycle methods in details.

The init method :

The init method is designed to be called only once. It is called when the servlet is first created, and not called again for each user request. So, it is used for one-time initializations, just as with the init method of applets.

The servlet is normally created when a user first invokes a URL corresponding to the servlet, but you can also specify that the servlet be loaded when the server is first started.

When a user invokes a servlet, a single instance of each servlet gets created, with each user request resulting in a new thread that is handed off to doGet or doPost as appropriate. The init method simply creates or loads some data that will be used throughout the life of the servlet.

The init method definition looks like this:

```
public void init() throws ServletException {  
    // Initialization code...  
}
```

The service method :

The service method is the main method to perform the actual task. The servlet container *i. e.* *webserver* calls the service method to handle requests coming from the client *browsers* and to write the formatted response back to the client.

Each time the server receives a request for a servlet, the server spawns a new thread and calls service. The service method checks the HTTP request type *GET, POST, PUT, DELETE, etc.* and calls doGet, doPost, doPut, doDelete, etc. methods as appropriate.

Here is the signature of this method:

```
public void service(ServletRequest request,  
                   ServletResponse response)  
    throws ServletException, IOException{  
}
```

The service method is called by the container and service method invokes doGe, doPost, doPut, doDelete, etc. methods as appropriate. So you have nothing to do with service method but you override either doGet or doPost depending on what type of request you receive from the client.

The doGet and doPost are most frequently used methods with in each service request. Here is the signature of these two methods.

The doGet Method

A GET request results from a normal request for a URL or from an HTML form that has no METHOD specified and it should be handled by doGet method.

```

public void doGet(HttpServletRequest request,
                  HttpServletResponse response)
    throws ServletException, IOException {
    // Servlet code
}

```

The doPost Method

A POST request results from an HTML form that specifically lists POST as the METHOD and it should be handled by doPost method.

```

public void doPost(HttpServletRequest request,
                  HttpServletResponse response)
    throws ServletException, IOException {
    // Servlet code
}

```

The destroy method :

The destroy method is called only once at the end of the life cycle of a servlet. This method gives your servlet a chance to close database connections, halt background threads, write cookie lists or hit counts to disk, and perform other such cleanup activities.

After the destroy method is called, the servlet object is marked for garbage collection. The destroy method definition looks like this:

```

public void destroy() {
    // Finalization code...
}

```

Architecture Diagram:

The following figure depicts a typical servlet life-cycle scenario.

- First the HTTP requests coming to the server are delegated to the servlet container.
- The servlet container loads the servlet before invoking the service method.
- Then the servlet container handles multiple requests by spawning multiple threads, each thread executing the service method of a single instance of the servlet.
