Software Architecture and Design

www.tutorialspoint.com
About the Tutorial

**Software Architecture** typically refers to the bigger structures of a software system and it deals with how multiple software processes cooperate to carry out their tasks. **Software Design** refers to the smaller structures and it deals with the internal design of a single software process.

By the end of this tutorial, the readers will develop a sound understanding of the concepts of software architecture and design concepts and will be in a position to choose and follow the right model for a given software project.

Audience

This tutorial is designed for all software professionals, architects, and senior system design engineers. Managers of architecture teams will also benefit from this tutorial.

Prerequisites

There are no exact prerequisites for this tutorial. Any software professional can go through this tutorial to get a bigger picture of how high quality software applications and products are designed.

   Communicating the Architecture Design ......................................................................................... 73
The architecture of a system describes its major components, their relationships (structures), and how they interact with each other. Software architecture and design is a process that includes several contributory factors such as Business strategy, quality attributes, human dynamics, design, and IT environment.

We can segregate Software Architecture and Design into two distinct phases: Software Architecture and Software Design. In **Architecture**, nonfunctional decisions are cast and separated by the functional requirements. In **Design**, functional requirements are accomplished.

**Software Architecture**

Architecture serves as a **blueprint for a system.** It provides an abstraction to manage the system complexity and establish a communication and coordination mechanism among components.

- It defines a **structured solution** to meet all the technical and operational requirements, while optimizing the common quality attributes like performance and security.

- It involves a set of significant decisions about the organization related to software development and each of these decisions can have a considerable impact on quality, maintainability, performance, and the overall success of the final product. These decisions comprise of:
  - Selection of structural elements and their interfaces by which the system is composed.
Behavior as specified in collaborations among those elements.

Composition of these structural and behavioral elements into large subsystem.

Architectural decisions align with business objectives.

Architectural styles that guide the organization.

**Software Design**

Software design provides a design plan that describes the elements of a system, how they fit, and work together to fulfill the requirement of the system. The objectives of having a design plan are as follows:

- To negotiate system requirements, and to set expectations with customers, marketing and management personnel.
- Act as a blueprint during the development process.
- Guide the implementation tasks, including detailed design, coding, integration, and testing.

It comes before the detailed design, coding, integration, and testing and after the domain analysis, requirements analysis, and risk analysis.

**Goals of Architecture**

The primary goal of the architecture is to identify requirements that affect the structure of the application. A well-laid architecture reduces the business risks associated with building a technical solution and builds a bridge between business and technical requirements. Some of the other goals are as follows:

- Expose the structure of the system, but hide its implementation details.
- Realize all the use-cases and scenarios.
- Try to address the requirements of various stakeholders.
• Handle both functional and quality requirements.
• Reduce the goal of ownership and improve the organization’s market position.
• Improve quality and functionality offered by the system.
• Improve external confidence in either the organization or system.

Limitations
Software architecture is still an emerging discipline within software engineering. It has the following limitations:
• Lack of tools and standardized ways to represent architecture
• Lack of analysis methods to predict whether architecture will result in an implementation that meets the requirements.
• Lack of awareness of the importance of architectural design to software development
• Lack of understanding of the role of software architect and poor communication among stakeholders.
• Lack of understanding of the design process, design experience and evaluation of design

Role of Software Architect
A Software Architect provides a solution that the technical team can create and design for the entire application. A software architect should have expertise in the following areas:

Design Expertise
• Expert in software design, including diverse methods and approaches such as object-oriented design, event-driven design, etc.
• Lead the development team and coordinate the development efforts for the integrity of the design.
• Should be able to review design proposals and tradeoffs among them.

Domain Expertise
• Expert on the system being developed and plan for software evolution.
• Assist in the requirement investigation process assuring completeness and consistency.
• Coordinate the definition of domain model for the system being developed.

Technology Expertise
• Expert on available technologies that helps in the implementation of the system.

• Coordinate the selection of programming language, framework, platforms, databases, etc.

Methodological Expertise

• Expert on software development methodologies that may be adopted during SDLC (Software Development Life Cycle).

• Choose the appropriate approaches for development that helps the entire team.

Hidden Role of Software Architect

• Facilitates the technical work among team members and reinforcing the trust relationship in the team.

• Information specialist who shares knowledge and has vast experience.

• Protect the team members from external forces that would distract them and bring less value to the project.

Deliverables of the Architect

• A clear, complete, consistent, and achievable set of functional goals

• A functional description of the system, with at least two layers of decomposition

• A concept for the system

• A design in the form of the system, with at least two layers of decomposition

• A notion of the timing, operator attributes, and the implementation and operation plans

• A document or process which ensures functional decomposition is followed, and the form of interfaces is controlled

Quality Attributes

Quality is a measure of excellence or the state of being free from deficiencies or defects. Quality attributes are system properties that are separate from the functionality of the system.

Implementing quality attributes makes it is easier to differentiate a good system from a bad one. Attributes are overall factors that affect runtime behavior, system design, and user experience. They can be classified as follows:

Static Quality Attributes

Reflect the structure of system and organization, directly related to architecture, design, source code. They are invisible to end-user, but affect the development and maintenance cost, e.g.: modularity, testability, maintainability, etc.
**Dynamic Quality Attributes**

Reflect the behavior of the system during its execution. They are directly related to system’s architecture, design, source code and also the configuration, deployment parameters, environment, and platform.

They are visible to the end-user and exist at runtime, e.g.: throughput, robustness, scalability, etc.

**Quality Scenarios**

Quality scenarios specify how to prevent a fault from becoming a failure. They can be divided into six parts based on their attribute specifications:

- **Source** An internal or external entity such as people, hardware, software, or physical infrastructure that generates the stimulus.

- **Stimulus** A condition that needs to be considered when it arrives on a system.

- **Environment** The stimulus occurs within certain conditions.

- **Artifact** A whole system or some part of it such as processors, communication channel, persistent storage, processes etc.

- **Response** An activity undertaken after the arrival of stimulus such as detect faults, recover from fault, disable event source etc.

- **Response measure** Should measure the occurred responses so that the requirements can be tested.

**Common Quality Attributes**

The following table lists the common quality attributes a software architecture must have.

<table>
<thead>
<tr>
<th>Category</th>
<th>Quality Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Design</td>
<td>Conceptual Integrity</td>
<td>Defines the consistency and coherence of the overall design. This includes the way components or modules are designed</td>
</tr>
<tr>
<td></td>
<td>Maintainability</td>
<td>Ability of the system to undergo changes with a degree of ease.</td>
</tr>
<tr>
<td></td>
<td>Reusability</td>
<td>Defines the capability for components and subsystems to be suitable for use in other applications</td>
</tr>
<tr>
<td></td>
<td>Interoperability</td>
<td>Ability of a system or different systems to operate successfully by communicating and exchanging</td>
</tr>
<tr>
<td>Run-time Qualities</td>
<td>System Qualities</td>
<td>User Qualities</td>
</tr>
<tr>
<td>-------------------</td>
<td>------------------</td>
<td>----------------</td>
</tr>
<tr>
<td>Run-time Qualities</td>
<td>System Qualities</td>
<td>User Qualities</td>
</tr>
<tr>
<td>Manageability</td>
<td>Supportability</td>
<td>Usability</td>
</tr>
<tr>
<td>Reliability</td>
<td>Testability</td>
<td></td>
</tr>
<tr>
<td>Scalability</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Security</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Performance</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Availability</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Run-time Qualities**
- **Manageability**: Defines how easy it is for system administrators to manage the application.
- **Reliability**: Ability of a system to remain operational over time.
- **Scalability**: Ability of a system to either handle increases in load without impact on the performance of the system, or the ability to be readily enlarged.
- **Security**: Capability of a system to prevent malicious or accidental actions outside of the designed usages.
- **Performance**: Indication of the responsiveness of a system to execute any action within a given time interval.
- **Availability**: Defines the proportion of time that the system is functional and working. It can be measured as a percentage of the total system downtime over a predefined period.

**System Qualities**
- **Supportability**: Ability of the system to provide information helpful for identifying and resolving issues when it fails to work correctly.
- **Testability**: Measure of how easy it is to create test criteria for the system and its components.

**User Qualities**
- **Usability**: Defines how well the application meets the requirements of the user and consumer by being intuitive.

**Architecture Quality**
- **Correctness**: Accountability for satisfying all the requirements of the system.

**Non-runtime Quality**
- **Portability**: Ability of the system to run under different computing environment.
- **Integrality**: Ability to make separately developed components of the system work correctly together.
- **Modifiability**: Ease with which each software system can accommodate changes to its software.

**Business quality attributes**
- **Cost and schedule**: Cost of the system with respect to time to market, expected project lifetime & utilization of legacy.
- **Marketability**: Use of system with respect to market competition.
Software architecture is described as the organization of a system, where the system represents a collection of components that accomplish a specific set of functions.

**Architectural Style**

The *architectural style*, also called as *architectural pattern*, is a set of principles which shapes an application. It defines an abstract framework for a family of system in terms of the pattern of structural organization. The architectural style

- Provides a lexicon of components and connectors with rules on how they can be combined.
- Improves partitioning and allows the reuse of design by giving solutions to frequently occurring problems.
- Describes a particular way to configure a collection of components (a module with well-defined interfaces, reusable, replaceable) and connectors (communication link between modules).

The software that is built for computer-based systems exhibit one of many architectural styles. Each style describes a system category that encompasses:

- A set of component types which perform a required function by the system
- A set of connectors (subroutine call, remote procedure call, data stream, socket) that enable communication, coordination, and cooperation among components
- Semantic constraints which define how components can be integrated to form the system
- A topological layout of the components indicating their runtime interrelationships

**Common Architectural Design**

The following table lists architectural styles that can be organized by their key focus area.

<table>
<thead>
<tr>
<th>Category</th>
<th>Architectural Design</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Message bus</td>
<td>Prescribes use of a software system that can receive and send messages using one or more communication channels</td>
</tr>
<tr>
<td>Communication</td>
<td>Service-Oriented Architecture (SOA)</td>
<td>Defines the applications that expose and consume functionality as a service using contracts and messages.</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------</td>
<td>--------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Deployment</td>
<td>Client/server</td>
<td>Separate the system into two applications, where the client makes requests to the server.</td>
</tr>
<tr>
<td></td>
<td>3-tier or N-tier</td>
<td>Separates the functionality into separate segments with each segment being a tier located on a physically separate computer.</td>
</tr>
<tr>
<td>Domain</td>
<td>Domain Driven Design</td>
<td>Focused on modeling a business domain and defining business objects based on entities within the business domain.</td>
</tr>
<tr>
<td>Structure</td>
<td>Component Based</td>
<td>Breakdown the application design into reusable functional or logical components that expose well-defined communication interfaces.</td>
</tr>
<tr>
<td></td>
<td>Layered</td>
<td>Divide the concerns of the application into stacked groups (layers).</td>
</tr>
<tr>
<td></td>
<td>Object oriented</td>
<td>Based on the division of responsibilities of an application or system into objects, each containing the data and the behavior relevant to the object.</td>
</tr>
</tbody>
</table>

**Types of Architecture**

There are four types of architecture from the viewpoint of an enterprise and collectively, these architectures are referred to as **enterprise architecture**.

- **Business architecture**: Defines the strategy of business, governance, organization, and key business processes within an enterprise and focuses on the analysis and design of business processes.

- **Application (software) architecture**: Serves as the blueprint for individual application systems, their interactions, and their relationships to the business processes of the organization.

- **Information architecture**: Defines the logical and physical data assets and data management resources.

- **Information technology (IT) architecture**: Defines the hardware and software building blocks that make up the overall information system of the organization.
Architecture Design Process

The architecture design process focuses on the decomposition of a system into components and their interactions to satisfy functional and nonfunctional requirements. The key inputs to software architecture design are:

- The requirements produced by the analysis tasks
- The hardware architecture (the software architect in turn provides requirements to the system architect, who configures the hardware architecture)

The result or output of the architecture design process is an **architectural description**. The basic architecture design process is composed of the following steps:

### Understand the Problem

- This is the most crucial step because it affects the quality of the design that follows.
- Without a clear understanding of the problem, it is not possible to create an effective solution.
- Many software projects and products are considered failures because they did not actually solve a valid business problem or have a recognizable return on investment (ROI).

### Identify Design Elements and their Relationships

- In this phase, build a baseline for defining the boundaries and context of the system.
- Decomposition of the system into its main components based on functional requirements. The decomposition can be modeled using a design structure matrix (DSM), which shows the dependencies between design elements without specifying the granularity of the elements.
- In this step, the first validation of the architecture is done by describing a number of system instances and this step is referred as functionality based architectural design.

### Evaluate the Architecture Design

- Each quality attribute is given an estimate so in order to gather qualitative measures or quantitative data, the design is evaluated.
- It involves evaluating the architecture for conformance to architectural quality attributes requirements.
- If all estimated quality attributes are as per the required standard, the architectural design process is finished.
- If not, the third phase of software architecture design is entered: architecture transformation. If the observed quality attribute does not meet its requirements, then a new design must be created.
