It is possible to have a select statement as part of the statement sequence of an outer select statement. Even if the case constants of the inner and outer select contain common values, no conflicts will arise.

Example

```
Module decisions
    Sub Main()
        'local variable definition
        Dim a As Integer = 100
        Dim b As Integer = 200
        Select a
            Case 100
                Console.WriteLine("This is part of outer case ")
                Select Case b
                    Case 200
                        Console.WriteLine("This is part of inner case ")
                End Select
            End Select
        Console.WriteLine("Exact value of a is : {0}", a)
        Console.WriteLine("Exact value of b is : {0}", b)
        Console.ReadLine()
    End Sub
End Module
```

When the above code is compiled and executed, it produces the following result:

```
This is part of outer case
This is part of inner case
Exact value of a is : 100
Exact value of b is : 200
```
