About the Tutorial

VBA stands for Visual Basic for Applications, an event-driven programming language from Microsoft. It is now predominantly used with Microsoft Office applications such as MS-Excel, MS-Word and MS-Access.

This tutorial teaches the basics of VBA. Each of the sections contain related topics with simple and useful examples.

Audience

This reference has been prepared for the beginners to help them understand the basics of VBA. This tutorial will provide enough understanding on VBA from where you can take yourself to a higher level of expertise.

Prerequisites

Before proceeding with this tutorial, you should install MS Office, particularly MS-Excel.

1. VBA – Overview

VBA stands for Visual Basic for Applications an event-driven programming language from Microsoft that is now predominantly used with Microsoft office applications such as MS-Excel, MS-Word, and MS-Access.

It helps techies to build customized applications and solutions to enhance the capabilities of those applications. The advantage of this facility is that you NEED NOT have visual basic installed on our PC, however, installing Office will implicitly help in achieving the purpose.

You can use VBA in all office versions, right from MS-Office 97 to MS-Office 2013 and also with any of the latest versions available. Among VBA, Excel VBA is the most popular. The advantage of using VBA is that you can build very powerful tools in MS Excel using linear programming.

Application of VBA

You might wonder why to use VBA in Excel as MS-Excel itself provides loads of inbuilt functions. MS-Excel provides only basic inbuilt functions which might not be sufficient to perform complex calculations. Under such circumstances, VBA becomes the most obvious solution.

For example, it is very hard to calculate the monthly repayment of a loan using Excel's built-in formulas. Rather, it is easy to program a VBA for such a calculation.
Accessing VBA Editor

In Excel window, press "ALT+F11". A VBA window opens up as shown in the following screenshot.
In this chapter, you will learn how to write a simple macro in a step by step manner.

**Step 1:** First, enable 'Developer' menu in Excel 20XX. To do the same, click File -> Options.

**Step 2:** Click 'Customize the Ribbon’ tab and check 'Developer'. Click 'OK'.

**Step 3:** The 'Developer' ribbon appears in the menu bar.
Step 4: Click the 'Visual Basic' button to open the VBA Editor.

Step 5: Start scripting by adding a button. Click Insert -> Select the button.

Step 6: Perform a right-click and choose 'properties'.
Step 7: Edit the name and caption as shown in the following screenshot.
Step 8: Now double-click the button and the sub-procedure outline will be displayed as shown in the following screenshot.
Step 9: Start coding by simply adding a message.

```vba
Private Sub say_helloworld_Click()
    MsgBox "Hi"
End Sub
```

Step 10: Click the button to execute the sub-procedure. The output of the sub-procedure is shown in the following screenshot.

Note: In further chapters, we will demonstrate using a simple button, as explained from step#1 to 10. Hence, it is important to understand this chapter thoroughly.
In this chapter, you will acquaint yourself with the commonly used excel VBA terminologies. These terminologies will be used in further modules, hence understanding each one of these is important.

**Modules**

Modules is the area where the code is written. This is a new Workbook, hence there aren’t any Modules.

To insert a Module, navigate to Insert -> Module. Once a module is inserted ‘module1’ is created.

Within the modules, we can write VBA code and the code is written within a Procedure. A Procedure/Sub Procedure is a series of VBA statements instructing what to do.
Procedure

Procedures are a group of statements executed as a whole, which instructs Excel how to perform a specific task. The task performed can be a very simple or a very complicated task. However, it is a good practice to break down complicated procedures into smaller ones.

The two main types of Procedures are Sub and Function.

Function

A function is a group of reusable code, which can be called anywhere in your program. This eliminates the need of writing the same code over and over again. This helps the programmers to divide a big program into a number of small and manageable functions.

Apart from inbuilt Functions, VBA allows to write user-defined functions as well and statements are written between Function and End Function.

Sub-procedures

Sub-procedures work similar to functions. While sub procedures DO NOT Return a value, functions may or may not return a value. Sub procedures CAN be called without call keyword. Sub procedures are always enclosed within Sub and End Sub statements.
Comments are used to document the program logic and the user information with which other programmers can seamlessly work on the same code in future.

It includes information such as developed by, modified by, and can also include incorporated logic. Comments are ignored by the interpreter while execution.

Comments in VBA are denoted by two methods.

- Any statement that starts with a Single Quote (') is treated as comment. Following is an example.

```vba
' This Script is invoked after successful login
' Written by: TutorialsPoint
' Return Value: True / False
```

- Any statement that starts with the keyword "REM". Following is an example.

```vba
REM This Script is written to Validate the Entered Input
REM Modified by: TutorialsPoint/user2
```
5. VBA — Message Box

The **MsgBox function** displays a message box and waits for the user to click a button and then an action is performed based on the button clicked by the user.

**Syntax**

```
MsgBox(prompt[,buttons][,title][,helpfile,context])
```

**Parameter Description**

- **Prompt** - A Required Parameter. A String that is displayed as a message in the dialog box. The maximum length of prompt is approximately 1024 characters. If the message extends to more than a line, then the lines can be separated using a carriage return character (Chr(13)) or a linefeed character (Chr(10)) between each line.

- **Buttons** - An Optional Parameter. A Numeric expression that specifies the type of buttons to display, the icon style to use, the identity of the default button, and the modality of the message box. If left blank, the default value for buttons is 0.

- **Title** - An Optional Parameter. A String expression displayed in the title bar of the dialog box. If the title is left blank, the application name is placed in the title bar.

- **Helpfile** - An Optional Parameter. A String expression that identifies the Help file to use for providing context-sensitive help for the dialog box.

- **Context** - An Optional Parameter. A Numeric expression that identifies the Help context number assigned by the Help author to the appropriate Help topic. If context is provided, helpfile must also be provided.

The **Buttons** parameter can take any of the following values:

- 0 vbOKOnly - Displays OK button only.
- 1 vbOKCancel - Displays OK and Cancel buttons.
- 2 vbAbortRetryIgnore - Displays Abort, Retry, and Ignore buttons.
- 3 vbYesNoCancel - Displays Yes, No, and Cancel buttons.
- 4 vbYesNo - Displays Yes and No buttons.
- 5 vbRetryCancel - Displays Retry and Cancel buttons.
- 16 vbCritical - Displays Critical Message icon.
- 32 vbQuestion - Displays Warning Query icon.
- 48 vbExclamation - Displays Warning Message icon.
• 64 vbInformation - Displays Information Message icon.
• 0 vbDefaultButton1 - First button is default.
• 256 vbDefaultButton2 - Second button is default.
• 512 vbDefaultButton3 - Third button is default.
• 768 vbDefaultButton4 - Fourth button is default.
• 0 vbApplicationModal Application modal - The current application will not work until the user responds to the message box.
• 4096 vbSystemModal System modal - All applications will not work until the user responds to the message box.

The above values are logically divided into four groups: The first group (0 to 5) indicates the buttons to be displayed in the message box. The second group (16, 32, 48, 64) describes the style of the icon to be displayed, the third group (0, 256, 512, 768) indicates which button must be the default, and the fourth group (0, 4096) determines the modality of the message box.

Return Values
The MsgBox function can return one of the following values which can be used to identify the button the user has clicked in the message box.

• 1 - vbOK - OK was clicked
• 2 - vbCancel - Cancel was clicked
• 3 - vbAbort - Abort was clicked
• 4 - vbRetry - Retry was clicked
• 5 - vbIgnore - Ignore was clicked
• 6 - vbYes - Yes was clicked
• 7 - vbNo - No was clicked

Example

Function MessageBox_Demo()
' Message Box with just prompt message
MsgBox("Welcome")

' Message Box with title, yes no and cancel buttoons
a = MsgBox("Do you like blue color?",3,"Choose options")
' Assume that you press No Button
msgbox ("The Value of a is " & a)
End Function

Output

Step 1: The above Function can be executed either by clicking the "Run" button on VBA Window or by calling the function from Excel Worksheet as shown in the following screenshot.

Step 2: A Simple Message box is displayed with a message "Welcome" and an "OK" Button
**Step 3:** After Clicking OK, yet another dialog box is displayed with a message along with "yes, no, and cancel" buttons.

![Dialog Box](image)

**Step 4:** After clicking the 'No' button, the value of that button (7) is stored as an integer and displayed as a message box to the user as shown in the following screenshot. Using this value, it can be understood which button the user has clicked.

![Message Box](image)
The **InputBox function** prompts the users to enter values. After entering the values, if the user clicks the OK button or presses ENTER on the keyboard, the InputBox function will return the text in the text box. If the user clicks the Cancel button, the function will return an empty string (""").

**Syntax**

```vba
InputBox(prompt[,title][,default][,xpos][,ypos][,helpfile,context])
```

**Parameter Description**

- **Prompt** - A required parameter. A String that is displayed as a message in the dialog box. The maximum length of prompt is approximately 1024 characters. If the message extends to more than a line, then the lines can be separated using a carriage return character (Chr(13)) or a linefeed character (Chr(10)) between each line.

- **Title** - An optional parameter. A String expression displayed in the title bar of the dialog box. If the title is left blank, the application name is placed in the title bar.

- **Default** - An optional parameter. A default text in the text box that the user would like to be displayed.

- **XPos** - An optional parameter. The position of X axis represents the prompt distance from the left side of the screen horizontally. If left blank, the input box is horizontally centered.

- **YPos** - An optional parameter. The position of Y axis represents the prompt distance from the left side of the screen vertically. If left blank, the input box is vertically centered.

- **Helpfile** - An optional parameter. A String expression that identifies the helpfile to be used to provide context-sensitive Help for the dialog box.

- **Context** - An optional parameter. A Numeric expression that identifies the Help context number assigned by the Help author to the appropriate Help topic. If context is provided, helpfile must also be provided.
Example
Let us calculate the area of a rectangle by getting values from the user at run time with the help of two input boxes (one for length and one for width).

```vba
Function findArea()
    Dim Length As Double
    Dim Width As Double

    Length = InputBox("Enter Length ", "Enter a Number")
    Width = InputBox("Enter Width", "Enter a Number")
    findArea = Length * Width
End Function
```

Output
Step 1: To execute the same, call using the function name and press Enter as shown in the following screenshot.
Step 2: Upon execution, the First input box (length) is displayed. Enter a value into the input box.

![Image of Enter Value dialog box with length input]

Step 3: After entering the first value, the second input box (width) is displayed.

![Image of Enter Value dialog box with width input]

Step 4: Upon entering the second number, click the OK button. The area is displayed as shown in the following screenshot.

![Image of Excel spreadsheet with calculated area]
Variable is a named memory location used to hold a value that can be changed during the script execution. Following are the basic rules for naming a variable.

- You must use a letter as the first character.
- You can't use a space, period (.), exclamation mark (!), or the characters @, &, $, # in the name.
- Name can't exceed 255 characters in length.
- You cannot use Visual Basic reserved keywords as variable name.

Syntax
In VBA, you need to declare the variables before using them.

```
Dim <<variable_name>> As <<variable_type>>
```

Data Types
There are many VBA data types, which can be divided into two main categories, namely numeric and non-numeric data types.

Numeric Data Types
Following table displays the numeric data types and the allowed range of values.

<table>
<thead>
<tr>
<th>Type</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Byte</td>
<td>0 to 255</td>
</tr>
<tr>
<td>Integer</td>
<td>-32,768 to 32,767</td>
</tr>
<tr>
<td>Long</td>
<td>-2,147,483,648 to 2,147,483,648</td>
</tr>
<tr>
<td>Single</td>
<td>-3.402823E+38 to -1.401298E-45 for negative values</td>
</tr>
<tr>
<td></td>
<td>1.401298E-45 to 3.402823E+38 for positive values</td>
</tr>
<tr>
<td>Double</td>
<td>-1.79769313486232e+308 to -4.94065645841247E-324 for negative values</td>
</tr>
</tbody>
</table>
Non-Numeric Data Types
Following table displays the non-numeric data types and the allowed range of values.

<table>
<thead>
<tr>
<th>Type</th>
<th>Range of Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>String (fixed length)</td>
<td>1 to 65,400 characters</td>
</tr>
<tr>
<td>String (variable length)</td>
<td>0 to 2 billion characters</td>
</tr>
<tr>
<td>Date</td>
<td>January 1, 100 to December 31, 9999</td>
</tr>
<tr>
<td>Boolean</td>
<td>True or False</td>
</tr>
<tr>
<td>Object</td>
<td>Any embedded object</td>
</tr>
<tr>
<td>Variant (numeric)</td>
<td>Any value as large as double</td>
</tr>
<tr>
<td>Variant (text)</td>
<td>Same as variable-length string</td>
</tr>
</tbody>
</table>

Example
Let us create a button and name it as 'Variables_demo' to demonstrate the use of variables.
Dim password As String
gpassword = "Admin#1"

Dim num As Integer
num = 1234

Dim BirthDay As Date
BirthDay = 30 / 10 / 2020

MsgBox "Passowrd is " & password & Chr(10) & "Value of num is " & num & Chr(10) & "Value of Birthday is " & BirthDay

End Sub

Output
Upon executing the script, the output will be as shown in the following screenshot.
Constant is a named memory location used to hold a value that CANNOT be changed during the script execution. If a user tries to change a Constant value, the script execution ends up with an error. Constants are declared the same way the variables are declared.

Following are the rules for naming a constant.

- You must use a letter as the first character.
- You can't use a space, period (.), exclamation mark (!), or the characters @, &, $, # in the name.
- Name can't exceed 255 characters in length.
- You cannot use Visual Basic reserved keywords as variable name.

**Syntax**

In VBA, we need to assign a value to the declared Constants. An error is thrown, if we try to change the value of the constant.

```
Const <<constant_name>> As <<constant_type>> = <<constant_value>>
```

**Example**

Let us create a button "Constant_demo" to demonstrate how to work with constants.

```
Private Sub Constant_demo_Click()
    Const MyInteger As Integer = 42
    Const myDate As Date = #2/2/2020#
    Const myDay As String = "Sunday"

    MsgBox "Integer is " & MyInteger & Chr(10) & "myDate is " & myDate & Chr(10) & "myDay is " & myDay

End Sub
```
Output

Upon executing the script, the output will be displayed as shown in the following screenshot.

![Screenshot of Excel dialog box displaying output](image-url)
An **Operator** can be defined using a simple expression - 4 + 5 is equal to 9. Here, 4 and 5 are called **operands** and + is called **operator**. VBA supports following types of operators:

- Arithmetic Operators
- Comparison Operators
- Logical (or Relational) Operators
- Concatenation Operators

### The Arithmetic Operators

Following arithmetic operators are supported by VBA:

Assume variable A holds 5 and variable B holds 10, then -

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>Adds the two operands</td>
<td>A + B will give 15</td>
</tr>
<tr>
<td>-</td>
<td>Subtracts the second operand from the first</td>
<td>A - B will give -5</td>
</tr>
<tr>
<td>*</td>
<td>Multiplies both the operands</td>
<td>A * B will give 50</td>
</tr>
<tr>
<td>/</td>
<td>Divides the numerator by the denominator</td>
<td>B / A will give 2</td>
</tr>
<tr>
<td>%</td>
<td>Modulus operator and the remainder after an integer division</td>
<td>B MOD A will give 0</td>
</tr>
<tr>
<td>^</td>
<td>Exponentiation Operator</td>
<td>B ^ A will give 100000</td>
</tr>
</tbody>
</table>
Arithmetic Operators – Example

Add a button and try the following example to understand all the arithmetic operators available in VBA.

```
Private Sub Constant_demo_Click()
    Dim a As Integer
    a = 5

    Dim b As Integer
    b = 10

    Dim c As Double

    c = a + b
    MsgBox ("Addition Result is " & c)

    c = a - b
    MsgBox ("Subtraction Result is " & c)

    c = a * b
    MsgBox ("Multiplication Result is " & c)

    c = b / a
    MsgBox ("Division Result is " & c)

    c = b Mod a
    MsgBox ("Modulus Result is " & c)

    c = b ^ a
    MsgBox ("Exponentiation Result is " & c)
End Sub
```

When you click the button or execute the above script, it will produce the following result.

Addition Result is 15
Subtraction Result is -5

Multiplication Result is 50
Division Result is 2

Modulus Result is 0

Exponentiation Result is 100000

**The Comparison Operators**

There are following comparison operators supported by VBA.

Assume variable A holds 10 and variable B holds 20, then -

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>==</td>
<td>Checks if the value of the two operands are equal or not. If yes, then the condition is true.</td>
<td>(A == B) is False.</td>
</tr>
<tr>
<td>&lt;&gt;</td>
<td>Checks if the value of the two operands are equal or not. If the values are not equal, then the condition is true.</td>
<td>(A &lt;&gt; B) is True.</td>
</tr>
<tr>
<td>&gt;</td>
<td>Checks if the value of the left operand is greater than the value of the right operand. If yes, then the condition is true.</td>
<td>(A &gt; B) is False.</td>
</tr>
<tr>
<td>&lt;</td>
<td>Checks if the value of the left operand is less than the value of the right operand. If yes, then the condition is true.</td>
<td>(A &lt; B) is True.</td>
</tr>
<tr>
<td>&gt;=</td>
<td>Checks if the value of the left operand is greater than or equal to the value of the right operand. If yes, then the condition is true.</td>
<td>(A &gt;= B) is False.</td>
</tr>
<tr>
<td>&lt;=</td>
<td>Checks if the value of the left operand is less than or equal to the value of the right operand. If yes, then the condition is true.</td>
<td>(A &lt;= B) is True.</td>
</tr>
</tbody>
</table>

**Comparison Operators – Example**

Try the following example to understand all the Comparison operators available in VBA.

```vba
Private Sub Constant_demo_Click()

    Dim a: a = 10

```
Dim b: b = 20
Dim c

If a = b Then
   MsgBox ("Operator Line 1 : True")
Else
   MsgBox ("Operator Line 1 : False")
End If

If a<>b Then
   MsgBox ("Operator Line 2 : True")
Else
   MsgBox ("Operator Line 2 : False")
End If

If a>b Then
   MsgBox ("Operator Line 3 : True")
Else
   MsgBox ("Operator Line 3 : False")
End If

If a<b Then
   MsgBox ("Operator Line 4 : True")
Else
   MsgBox ("Operator Line 4 : False")
End If

If a>=b Then
   MsgBox ("Operator Line 5 : True")
Else
   MsgBox ("Operator Line 5 : False")
End If
If a<=b Then
    MsgBox ("Operator Line 6 : True")
Else
    MsgBox ("Operator Line 6 : False")
End If
End Sub

When you execute the above script, it will produce the following result.

Operator Line 1 : False
Operator Line 2 : True
Operator Line 3 : False
Operator Line 4 : True
Operator Line 5 : False
Operator Line 6 : True

The Logical Operators

Following logical operators are supported by VBA.

Assume variable A holds 10 and variable B holds 0, then -

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>AND</td>
<td>Called Logical AND operator. If both the conditions are True, then the Expression is true.</td>
<td>a&lt;&gt;0 AND b&lt;&gt;0 is False.</td>
</tr>
<tr>
<td>OR</td>
<td>Called Logical OR Operator. If any of the two conditions are True, then the condition is true.</td>
<td>a&lt;&gt;0 OR b&lt;&gt;0 is true.</td>
</tr>
<tr>
<td>NOT</td>
<td>Called Logical NOT Operator. Used to reverse the logical state of its operand. If a condition is true, then Logical NOT operator will make false.</td>
<td>NOT(a&lt;&gt;0 OR b&lt;&gt;0) is false.</td>
</tr>
</tbody>
</table>
XOR
Called Logical Exclusion. It is the combination of NOT and OR Operator. If one, and only one, of the expressions evaluates to be True, the result is True. (a<>0 XOR b<>0) is false.

Logical Operators — Example
Try the following example to understand all the Logical operators available in VBA by creating a button and adding the following function.

Private Sub Constant_demo_Click()
    Dim a As Integer
    a = 10
    Dim b As Integer
    b = 0

    If a <> 0 And b <> 0 Then
        MsgBox ("AND Operator Result is : True")
    Else
        MsgBox ("AND Operator Result is : False")
    End If

    If a <> 0 Or b <> 0 Then
        MsgBox ("OR Operator Result is : True")
    Else
        MsgBox ("OR Operator Result is : False")
    End If

    If Not (a <> 0 Or b <> 0) Then
        MsgBox ("NOT Operator Result is : True")
    Else
        MsgBox ("NOT Operator Result is : False")
    End If

    If (a <> 0 Xor b <> 0) Then
        MsgBox ("XOR Operator Result is : True")
End Sub
Else
    MsgBox ("XOR Operator Result is : False")
End If
End Sub

When you save it as .html and execute it in the Internet Explorer, then the above script will produce the following result.

AND Operator Result is : False
OR Operator Result is : True
NOT Operator Result is : False
XOR Operator Result is : True

The Concatenation Operators

Following Concatenation operators are supported by VBA.

Assume variable A holds 5 and variable B holds 10 then -

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>Adds two Values as Variable. Values are Numeric</td>
<td>A + B will give 15</td>
</tr>
<tr>
<td>&amp;</td>
<td>Concatenates two Values</td>
<td>A &amp; B will give 510</td>
</tr>
</tbody>
</table>

Assume variable A = "Microsoft" and variable B = "VBScript", then -

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>Concatenates two Values</td>
<td>A + B will give MicrosoftVBScript</td>
</tr>
<tr>
<td>&amp;</td>
<td>Concatenates two Values</td>
<td>A &amp; B will give MicrosoftVBScript</td>
</tr>
</tbody>
</table>

**Note:** Concatenation Operators can be used for both numbers and strings. The output depends on the context, if the variables hold numeric value or string value.

Concatenation Operators

Following table shows all the Concatenation operators supported by VBScript language. Assume variable A holds 5 and variable B holds 10, then -

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>Concatenates two Values</td>
<td>A + B will give MicrosoftVBScript</td>
</tr>
<tr>
<td>&amp;</td>
<td>Concatenates two Values</td>
<td>A &amp; B will give MicrosoftVBScript</td>
</tr>
</tbody>
</table>
### VBA

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>Adds two Values as Variable. Values are Numeric</td>
<td>A + B will give 15</td>
</tr>
<tr>
<td>&amp;</td>
<td>Concatenates two Values</td>
<td>A &amp; B will give 510</td>
</tr>
</tbody>
</table>

**Example**

Try the following example to understand the Concatenation operator available in VBScript:

```vba
Private Sub Constant_demo_Click()
    Dim a as Integer : a = 5
    Dim b as Integer : b = 10
    Dim c as Integer

    c = a + b
    msgbox ("Concatenated value:1 is " & c) 'Numeric addition
    c = a & b
    msgbox ("Concatenated value:2 is " & c) 'Concatenate two numbers
End Sub
```

Try the following example to understand all the Logical operators available in VBA by creating a button and adding the following function.

**Concatenated value:1 is 15**

**Concatenated value:2 is 510**

Concatenation can also be used for concatenating two strings. Assume variable A = "Microsoft" and variable B = "VBScript" then -

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>Concatenates two Values</td>
<td>A + B will give MicrosoftVBScript</td>
</tr>
<tr>
<td>&amp;</td>
<td>Concatenates two Values</td>
<td>A &amp; B will give MicrosoftVBScript</td>
</tr>
</tbody>
</table>

**Example**
Try the following example to understand all the Logical operators available in VBA by creating a button and adding the following function.

```vba
Private Sub Constant_demo_Click()
    Dim a as String : a = "Microsoft"
    Dim b as String : b = "VBScript"
    Dim c as String

    c=a+b
    msgbox("Concatenated value:1 is " & c) 'addition of two Strings
    c=a&b
    msgbox("Concatenated value:2 is " & c) 'Concatenate two String
End Sub
```

When you save it as .html and execute it in the Internet Explorer, then the above script will produce the following result.

```
Concatenated value:1 is MicrosoftVBScript

Concatenated value:2 is MicrosoftVBScript
```
