XPATH
query language for XML

www.tutorialspoint.com
**About the Tutorial**

XPath is a query language that is used for traversing through an XML document. It is used commonly to search particular elements or attributes with matching patterns.

This tutorial explains the basics of XPath. It contains chapters discussing all the basic components of XPath with suitable examples.

**Audience**

This tutorial has been designed for beginners to help them understand the basic concepts related to XPath. This tutorial will give you enough understanding on XPath from where you can take yourself to higher levels of expertise.

**Prerequisites**

Before proceeding with this tutorial, you should have basic knowledge of XML, HTML, and JavaScript.

Before learning XPath, we should first understand XSL which stands for Extensible Stylesheet Language. It is similar to XML as CSS is to HTML.

**Need for XSL**

In case of HTML documents, tags are predefined such as table, div, span, etc. The browser knows how to add style to them and display them using CSS styles. But in case of XML documents, tags are not predefined. In order to understand and style an XML document, **World Wide Web Consortium (W3C)** developed XSL which can act as an XML-based Stylesheet Language. An XSL document specifies how a browser should render an XML document.

Following are the main parts of XSL:

- **XSLT** — used to transform XML documents into various other types of document.
- **XPath** — used to navigate XML documents.
- **XSL-FO** — used to format XML documents.

**What is XPath?**

XPath is an official recommendation of the World Wide Web Consortium (W3C). It defines a language to find information in an XML file. It is used to traverse elements and attributes of an XML document. XPath provides various types of expressions which can be used to enquire relevant information from the XML document.

- **Structure Definitions** — XPath defines the parts of an XML document like element, attribute, text, namespace, processing-instruction, comment, and document nodes
- **Path Expressions** — XPath provides powerful path expressions select nodes or list of nodes in XML documents.
- **Standard Functions** — XPath provides a rich library of standard functions for manipulation of string values, numeric values, date and time comparison, node and QName manipulation, sequence manipulation, Boolean values etc.
- **Major part of XSLT** — XPath is one of the major elements in XSLT standard and is must have knowledge in order to work with XSLT documents.
- **W3C recommendation** — XPath is an official recommendation of World Wide Web Consortium (W3C).
One should keep the following points in mind, while working with XPath:

- XPath is core component of XSLT standard.
- XSLT cannot work without XPath.
- XPath is basis of XQuery and XPointer.
2. XPath — Expression

An XPath expression generally defines a pattern in order to select a set of nodes. These patterns are used by XSLT to perform transformations or by XPointer for addressing purpose.

XPath specification specifies seven types of nodes which can be the output of execution of the XPath expression.

- Root
- Element
- Text
- Attribute
- Comment
- Processing Instruction
- Namespace

XPath uses a path expression to select node or a list of nodes from an XML document.

Following is the list of useful paths and expression to select any node/ list of nodes from an XML document.

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node-name</td>
<td>Select all nodes with the given name &quot;nodename&quot;</td>
</tr>
<tr>
<td>/</td>
<td>Selection starts from the root node</td>
</tr>
<tr>
<td>//</td>
<td>Selection starts from the current node that match the selection</td>
</tr>
<tr>
<td>.</td>
<td>Selects the current node</td>
</tr>
<tr>
<td>..</td>
<td>Selects the parent of the current node</td>
</tr>
<tr>
<td>@</td>
<td>Selects attributes</td>
</tr>
<tr>
<td>student</td>
<td>Example: Selects all nodes with the name &quot;student&quot;</td>
</tr>
</tbody>
</table>
XPath

<table>
<thead>
<tr>
<th>class/student</th>
<th>Example: Selects all student elements that are children of class</th>
</tr>
</thead>
<tbody>
<tr>
<td>//student</td>
<td>Selects all student elements no matter where they are in the document</td>
</tr>
</tbody>
</table>

Example

In this example, we've created a sample XML document, students.xml and its stylesheet document students.xsl which uses the XPath expressions under select attribute of various XSL tags to get the values of roll no, firstname, lastname, nickname and marks of each student node.

students.xml

```xml
<?xml version="1.0"?>
<?xml-stylesheet type="text/xsl" href="students.xsl"?>
<class>
    <student rollno="393">
        <firstname>Dinkar</firstname>
        <lastname>Kad</lastname>
        <nickname>Dinkar</nickname>
        <marks>85</marks>
    </student>
    <student rollno="493">
        <firstname>Vaneet</firstname>
        <lastname>Gupta</lastname>
        <nickname>Vinni</nickname>
        <marks>95</marks>
    </student>
    <student rollno="593">
        <firstname>Jasvir</firstname>
        <lastname>Singh</lastname>
        <nickname>Jazz</nickname>
        <marks>90</marks>
    </student>
</class>
```
students.xsl

```xml
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
xmlns:xsl="http://www.w3.org/1999/XSL/Transform">

<xsl:template match="/">
  <html>
    <body>
      <h2>Students</h2>
      <table border="1">
        <tr bgcolor="#9acd32">
          <th>Roll No</th>
          <th>First Name</th>
          <th>Last Name</th>
          <th>Nick Name</th>
          <th>Marks</th>
        </tr>
        <xsl:for-each select="class/student">
          <tr>
            <td><xsl:value-of select="@rollno" /></td>
            <td><xsl:value-of select="firstname" /></td>
            <td><xsl:value-of select="lastname" /></td>
            <td><xsl:value-of select="nickname" /></td>
            <td><xsl:value-of select="marks" /></td>
          </tr>
        </xsl:for-each>
      </table>
    </body>
  </html>
</xsl:template>
</xsl:stylesheet>
```
Verify the output

<table>
<thead>
<tr>
<th>Roll No</th>
<th>First Name</th>
<th>Last Name</th>
<th>Nick Name</th>
<th>Marks</th>
</tr>
</thead>
<tbody>
<tr>
<td>393</td>
<td>Dinkar</td>
<td>Kad</td>
<td>Dinkar</td>
<td>85</td>
</tr>
<tr>
<td>493</td>
<td>Vaneet</td>
<td>Gupta</td>
<td>Vinni</td>
<td>95</td>
</tr>
<tr>
<td>593</td>
<td>Jasvir</td>
<td>Singh</td>
<td>Jazz</td>
<td>90</td>
</tr>
</tbody>
</table>
In this chapter, we'll see the XPath expression in details covering common types of Nodes, XPath defines and handles.

<table>
<thead>
<tr>
<th>S.N.</th>
<th>Node Type &amp; Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><strong>Root</strong> Root element node of an XML Document.</td>
</tr>
<tr>
<td>2</td>
<td><strong>Element</strong> Element node.</td>
</tr>
<tr>
<td>3</td>
<td><strong>Text</strong> Text of an element node.</td>
</tr>
<tr>
<td>4</td>
<td><strong>Attribute</strong> Attribute of an element node.</td>
</tr>
<tr>
<td>5</td>
<td><strong>Comment</strong> Comment</td>
</tr>
</tbody>
</table>

Let us now understand the nodes in detail.

**XPath Root Node**

Following are the ways to get root element and do the processing afterwards.

**Use Wildcard**

Use `/*`, wild card expression to select the root node.

```xml
<p><xsl:value-of select="name(/*)"/></p>
```

**Use Name**

**Use /class**, to select root node by name.

```xml
<p><xsl:value-of select="name(/class)"/></p>
```
Use Name with wild card

Use /class/*, select all element under root node.

```xml
<p><xsl:value-of select="name(/class/*)"/></p>
```

Example

In this example, we've created a sample XML document `students.xml` and its stylesheet document `students.xsl` which uses the XPath expressions.

Following is the sample XML used.

```xml
students.xml

<?xml version="1.0"?>
<?xml-stylesheet type="text/xsl" href="students.xsl"?>
<class>
  <student rollno="393">
    <firstname>Dinkar</firstname>
    <lastname>Kad</lastname>
    <nickname>Dinkar</nickname>
    <marks>85</marks>
  </student>
  <student rollno="493">
    <firstname>Vaneet</firstname>
    <lastname>Gupta</lastname>
    <nickname>Vinni</nickname>
    <marks>95</marks>
  </student>
  <student rollno="593">
    <firstname>Jasvir</firstname>
    <lastname>Singh</lastname>
    <nickname>Jazz</nickname>
    <marks>90</marks>
  </student>
</class>
```
students.xsl

```xml
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
    xmlns:xsl="http://www.w3.org/1999/XSL/Transform">
    <xsl:template match="/"
    xmlns:xsl="http://www.w3.org/1999/XSL/Transform">
        <html>
            <body>
                <h3>Root Element. Xpath expression = "/"</h3>
                <p><xsl:value-of select="name(/*)"/></p>
                <h3>Root Element. Xpath expression = "/class"</h3>
                <p><xsl:value-of select="name(/class)"/></p>
                <h3>Details of each Students. Xpath expression = "/class/*"</h3>
                <table border="1">
                    <tr bgcolor="#9acd32">
                        <th>Roll No</th>
                        <th>First Name</th>
                        <th>Last Name</th>
                        <th>Nick Name</th>
                        <th>Marks</th>
                    </tr>
                    <xsl:for-each select="/class/*">
                        <tr>
                            <td>
                                <xsl:value-of select="@rollno"/>
                            </td>
                            <td><xsl:value-of select="firstname"/></td>
                            <td><xsl:value-of select="lastname"/></td>
                            <td><xsl:value-of select="nickname"/></td>
                            <td><xsl:value-of select="marks"/></td>
                        </tr>
                    </xsl:for-each>
                </table>
            </body>
        </html>
    </xsl:template>
</xsl:stylesheet>
```
Verify the output

Root Element. Xpath expression = "/*"

class

Root Element. Xpath expression = "/*class"

class

Details of each Students. Xpath expression = "/*class/*"

<table>
<thead>
<tr>
<th>Roll No</th>
<th>First Name</th>
<th>Last Name</th>
<th>Nick Name</th>
<th>Marks</th>
</tr>
</thead>
<tbody>
<tr>
<td>393</td>
<td>Dinkar</td>
<td>Kad</td>
<td>Dinkar</td>
<td>85</td>
</tr>
<tr>
<td>493</td>
<td>Vaneet</td>
<td>Gupta</td>
<td>Vinni</td>
<td>95</td>
</tr>
<tr>
<td>593</td>
<td>Jasvir</td>
<td>Singh</td>
<td>Jazz</td>
<td>90</td>
</tr>
</tbody>
</table>
